(m3/tc0,)

applications, such as biomass,

natural gas power plants, and the oilsands, it may be possible to generate more water than is consumed. If this water can be treated and reused within the same industrial process or for some other beneficial purpose, CCUS can provide a net benefit to water supplies. However, any generated water which cannot be used

must be appropriately managed, for example through disposal.

Visualization of annual median runoff and availability for the Peace, Bow, and Red Deer Rivers, which vary seasonally

and annually.

Many CCUS production facilities are proposed across Alberta. Using a 2050 time horizon, Figure 4 compares water that is available for new uses to the anticipated consumptive water demands of proposed CCUS development for the Red Deer River Basin, which are expected to require new water licences. The Red Deer River serves as an illustrative example of a basin nearing its maximum allocation capacity. Other rivers exhibit unique patterns of water availability and demand. 100 **AVAILABLE** WATER* *Based on the 80 allocation limit This demand in the Approved could stress Water Management a local area. impact on water availability. Alternatively, carbon capture projects which generate more water than they consume could lead to net-positive impacts on water availability. For each project, a good understanding is required of its basin-specific water context as well as its potential water impacts. **AVAILABLE VOLUME** NONE LOW **MEDIUM** HIGH **VERY HIGH** PROPOSED CO. **CAPTURE CAPACITY BY** PROJECT (Mt CO₂/yr) 0-1.5 1.5-4

carbon capture projects have the potential to reduce the net water consumption of hydrogen development, assuming that water recovered from the capture processes can be used to offset the demands for hydrogen production. For both hydrogen and CCUS development, water impacts, risks, and opportunities should be analyzed on a location-specific basis. **POTENTIAL** WATER DEMAND LOW **CCUS** MID HIGH CCUS + **POTENTIAL HYDROGEN** CUMULATIVE

WaterSMART's 2023 study on the water impacts of hydrogen development in Alberta estimated that it could potentially consume between 121,100 and

503,360 dam³/yr.³ When the announced carbon capture projects are layered onto

WATER SUPPLY FOR CCUS In Alberta, the amount of water available for use varies greatly by location, time of year, and year over year. This variability is managed by regulators and users to meet ecological and human needs while making water available for

economic development. Rivers in southern Alberta, which flow through more populated areas, face higher competition for water

- CCUS has been recognized as one of the four pillars of the global energy transition, alongside renewable power generation, bioenergy, and hydrogen.1 In Alberta, the province's Hydrogen Roadmap explicitly links hydrogen development and CCUS,² a position which has been echoed by industry.
